# Building a Router with RPI5

**Author(s):** Louis Ouellet

A compact, high-performance home/SMB router built on **Raspberry Pi 5** with the **Radxa Dual 2.5G Router HAT**. Runs on Raspberry Pi OS with a lean Linux stack (**ifupdown + iptables + dnsmasq**) and optional services like **Pi-hole**, **Unbound** (recursive DNS), and a **Wi-Fi AP**. The project includes shell scripts and documentation to reproduce the setup end-to-end, including **NVMe migration** for reliability and speed.

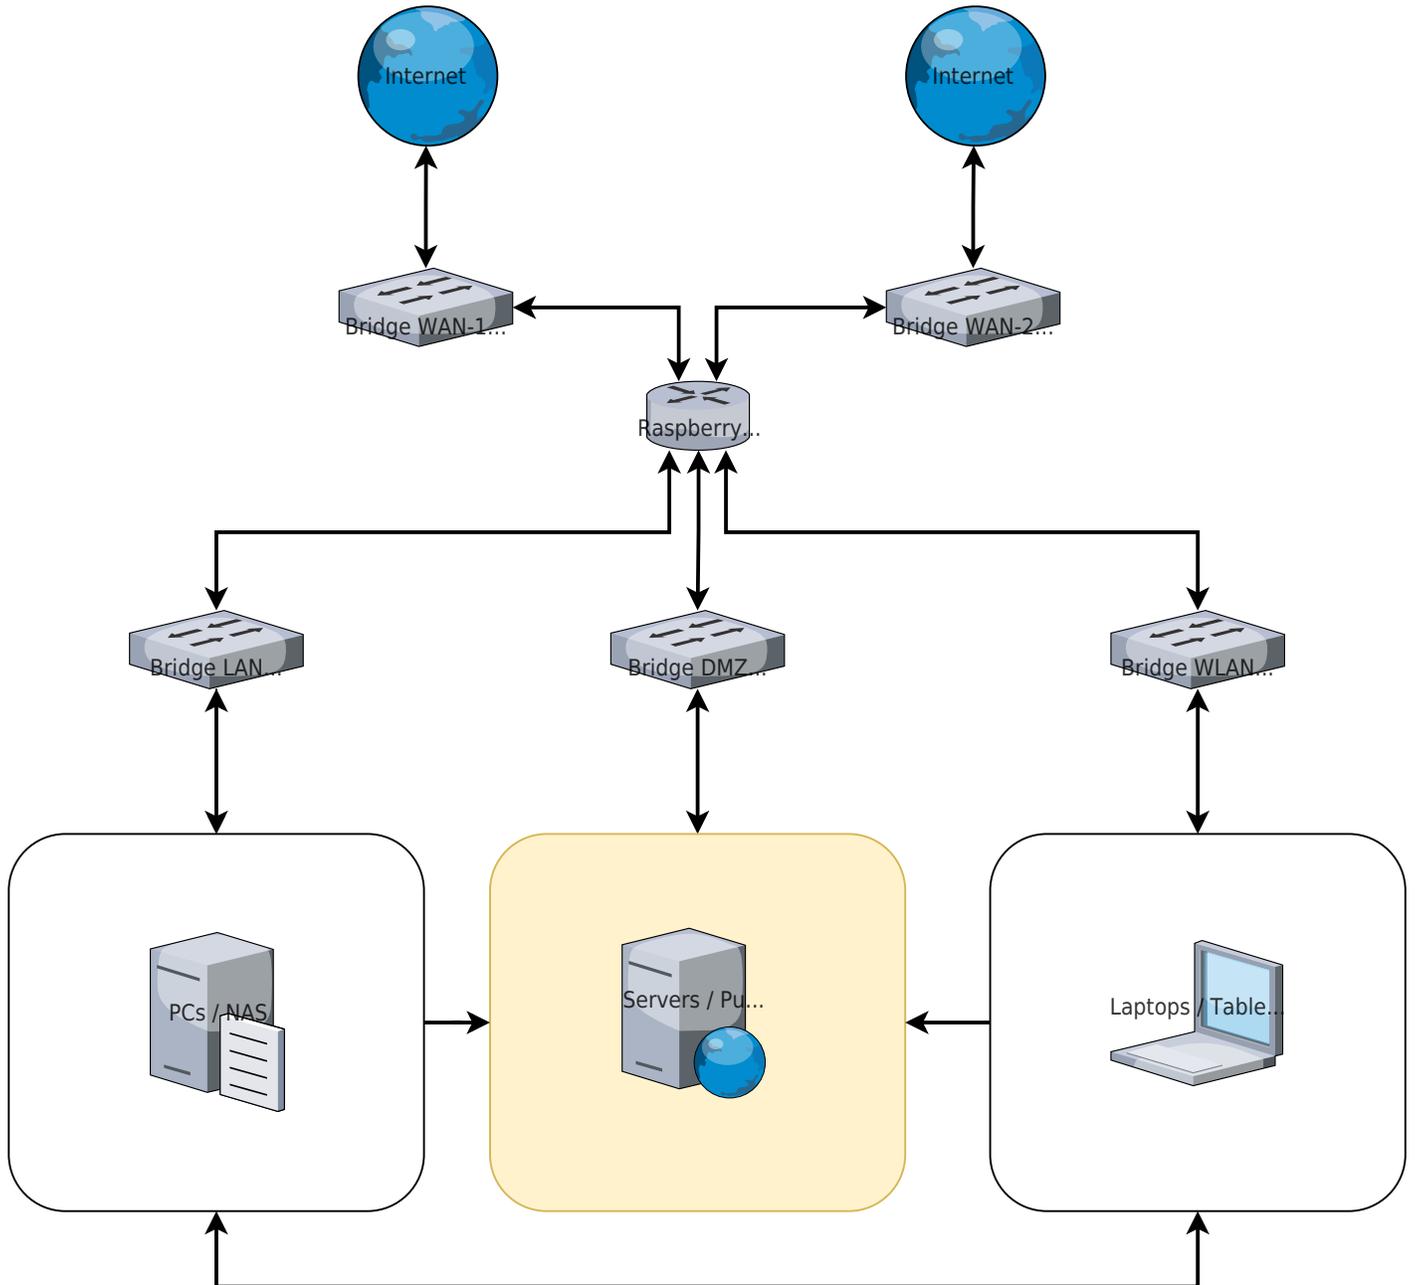

## Features

- **Three-zone routing:** WAN (eth0), LAN (eth1), DMZ (eth2)
- **Clean networking:** ifupdown for addresses, iptables for firewall/NAT, dnsmasq for

## DHCP

- **sane defaults**: secure INPUT policy, LAN-only SSH, DHCP/DNS per zone, NAT out via WAN
- **NVMe boot/migration**: scripted SD→NVMe clone, resize, and boot order tweak
- **Optional Pi-hole**: Pi-hole owns :53; system dnsmasq does DHCP + local DNS on :5353
- **Optional Unbound**: local recursive resolver on 127.0.0.1#5335 (DNSSEC, no 3rd-party upstreams)
- **Optional Wi-Fi AP**: guest (routed subnet on wlan0) or bridged (LAN extender via br0)
- **Idempotent scripts**: re-runnable installers that won't clobber working configs
- **Firewall extras**: examples for port-forward, DNS-redirect, and guest isolation

## Network Topology

## Defaults & Behavior

- **Subnets:** LAN 192.168.10.0/24, DMZ 192.168.20.0/24 (guest Wi-Fi 192.168.30.0/24 if enabled)
- **Gateway IPs:** LAN 192.168.10.1, DMZ 192.168.20.1, Wi-Fi 192.168.30.1
- **DHCP pools:** .100-.200 per subnet (configurable in scripts)
- **Firewall:**
  - INPUT: **DROP** by default; allow loopback, established/related, DHCP/DNS from LAN/DMZ, **SSH from LAN only**
  - FORWARD: allow LAN/DMZ→WAN; block unsolicited WAN→LAN/DMZ; LAN↔DMZ

blocked unless explicitly allowed

◦ NAT: MASQUERADE out via WAN

- **Pi-Hole mode (optional)**: Pi-hole/FTL on **:53**; system dnsmasq on **:5353** serves local zones; Pi-hole forwards lan/dmz to 127.0.0.1#5353
- **Unbound (optional)**: Pi-hole upstream set to 127.0.0.1#5335 for local recursion (DNSSEC in Unbound)

## Quick Start

Requires Raspberry Pi OS (Bookworm), RPi5 with Radxa Dual 2.5G HAT, and basic console access.

```
# 1) Get the installer
curl -fsSL https://raw.githubusercontent.com/LaswitchTech/router-pi5/stable/install.sh -o install.sh
chmod +x install.sh

# 2) Run base router setup (ifupdown + iptables + dnsmasq)
sudo ./install.sh

# 3) (Optional) Add services later
# Pi-hole DNS front-end
sudo ./add-pihole.sh
# Unbound recursive resolver
sudo ./add-unbound.sh
# Guest Wi-Fi AP (routed)
sudo ./add-ap-wifi-guest.sh
# Bridged Wi-Fi AP (LAN extender)
sudo ./add-ap-wifi-bridge.sh
```

**Heads-up:** if you already installed Pi-hole, it binds port **53**. The system dnsmasq used for DHCP must be moved to **port 5353** (the scripts handle this). To diagnose conflicts: `sudo ss -lunp '( sport = :53 or sport = :5353 )'`

## Documentation

Review the [full documentation](#) including:

- **Installation** (router base, NVMe migration)
- **Pi-hole integration** (dnsmasq → 5353, local zones, optional DNS redirect)
- **Unbound** (secure recursion, DNSSEC)
- **Wi-Fi AP** (guest routed vs bridged)
- **Port forwarding & hairpin NAT** examples
- **Troubleshooting** (port 53 conflicts, DHCP scope, PCIe enable on Pi 5)

## Hardware, Parts & Costs

Brand	Part	Vendor	Qty	Price
Raspberry Pi	5 (4-8 GB)	<a href="#">Amazon</a>	1	143.00 C\$
Raspberry Pi	5 Active Cooler	<a href="#">Amazon</a>	1	17.31 C\$
Radxa	Dual 2.5G Router HAT	<a href="#">AliExpress</a>	1	60.68 C\$
Radxa	Power DC12 60W	<a href="#">AliExpress</a>	1	17.89 C\$
			<b>Total</b>	238.88 \$CAD

## Gallery

## Roadmap

- Merge add-on scripts behind **install.sh flags** (e.g., `-with-pihole`, `-with-unbound`, `-with-ap-guest|bridge`)
- Optional **PHP admin** for templating configs & safe reloads (diff + rollback)
- SQM/CAKE for bufferbloat control
- Support for redundant WANs
- WireGuard site-to-site & remote-access presets
- VLAN templates and multiple SSID support (hostapd multi-BSS)

## Troubleshooting Snippets

```
# Who's using port 53 / 5353?
```

```
sudo ss -lntup '( sport = :53 or sport = :5353 )'  
sudo ss -lunp '( sport = :53 or sport = :5353 )'  
  
# Pi-hole DNS reload + logs  
sudo pihole reload dns  
journalctl -u pihole-FTL -n 50 --no-pager  
  
# dnsmasq status & lease file  
systemctl status dnsmasq  
cat /var/lib/misc/dnsmasq.leases
```

## License & Credits

Code and docs are in the repo; see **LICENSE** file for details. Thanks to the Raspberry Pi, Radxa, and open-source communities.
